

GEMINI HISTORICAL ARTIFACT DESCRIPTOR

1. INTRODUCTION

1.1 Overview

The Gemini Historical Artifact Descriptor is an advanced multimodal artificial intelligence application designed to generate academic-style historical documentation from artifact images. The system leverages Google's Gemini 2.5 Flash model to analyze visual and textual inputs simultaneously. In traditional historical research workflows, artifact documentation involves manual observation, contextual research, material analysis, and structured writing. This process is time-intensive and requires subject-matter expertise. The proposed system automates this workflow by integrating computer vision capabilities with natural language generation.

1.2 Purpose

This project demonstrates the interdisciplinary integration of artificial intelligence, digital humanities, web technologies, and secure API-based model deployment. It allows users to upload an artifact image, provide contextual instructions, and generate a structured 1000-word academic blog-style description. The generated content includes historical background, stylistic analysis, cultural context, comparative evaluation, and scholarly interpretation.

2. IDEATION PHASE

2.1 Problem Identification

Museums, academic institutions, and cultural heritage organizations manage large repositories of historical artifacts. Documenting each artifact manually requires historians to examine visual patterns, identify cultural markers, assess material composition, and research the socio-political context of the artifact's time period. Such manual documentation is not scalable for large archives.

Furthermore, students and researchers often struggle with structuring their artifact analysis into formal academic prose. The absence of automated documentation tools limits efficiency in digital archiving initiatives. Therefore, there is a need for a system that combines multimodal AI capabilities with an accessible web interface to generate structured historical narratives efficiently.

2.2 Brainstorming

Brainstorming is conducted during the ideation phase to generate innovative, practical, and scalable solutions for AI-based artifact documentation. The purpose is to explore multiple technical, functional, and user-experience possibilities before finalizing the implementation strategy.

Problem Identified:

Manual historical artifact documentation is time-consuming and requires subject expertise.

Initial Brainstorm Question:

“How can we use multimodal AI to automate structured academic descriptions from artifact images?”

3. REQUIREMENT ANALYSIS

3.1 Customer Journey Map

Scenario 1: Describing an Ancient Egyptian Artifact

A historian specializing in Ancient Egypt opens the Gemini Historical Artifact Description app and inputs "Tutankhamun's Golden Mask" with a 1200-word count. As the app generates the content, it shares a fascinating historical fact. The AI quickly delivers a detailed and insightful description. The historian reviews the well-crafted content and incorporates it into their research or publication, ready to share with their audience.

Scenario 2: Crafting a Renaissance Artifact Description

A museum curator looking for detailed descriptions of Renaissance artifacts uses the Gemini Historical Artifact Description app, inputting "Leonardo da Vinci's Notebook" and specifying an 800-word count. The app provides an intriguing historical fact while generating the content. The AI produces a concise yet informative description filled with historical context and artistic significance. The curator finds the description valuable and incorporates it into the museum's exhibition materials.

Scenario 3: Developing a Medieval Artifact Description

A medieval history enthusiast accesses the Gemini Historical Artifact Description app to generate new content for their blog. They enter "The Bayeux Tapestry" as the topic and select a 1500-word count. The app entertains with a historical fact during the content creation process. The AI delivers a comprehensive and well-detailed description. The enthusiast reviews the high-quality content and publishes it on their history blog, confident it will engage and inform their readers.

The primary objective of this project is to design and develop a multimodal AI application capable of generating detailed academic descriptions of historical artifacts using image and text inputs.

Specific objectives include: 1) Integrating Google Gemini API for multimodal analysis. 2) Designing a user-friendly interface using Streamlit. 3) Ensuring secure API key management using environment variables. 4) Enforcing academic writing tone using system-level prompt engineering. 5) Generating structured outputs exceeding 1000 words with contextual depth.

3.2 Solution Requirements

Functional Requirements:

- Upload vehicle image
- Process image data
- Send structured prompt to Gemini Flash
- Generate AI-based output
- Display formatted results

Non-Functional Requirements:

- Fast response time
- Secure API integration
- User-friendly interface
- Scalable architecture

4. PROJECT DESIGN

4.1 Project Solution Fit

Recent advancements in multimodal generative AI systems have enabled simultaneous understanding of textual and visual data. Transformer-based large language models have evolved from pure text-only systems to multimodal architectures capable of interpreting complex visual contexts.

The Gemini model family represents an evolution in this domain, offering high-speed inference and multimodal reasoning capabilities. Applications of such models have been observed in education, content generation, automated tutoring, digital design, and cultural heritage preservation.

4.2 Proposed Solution

Python programming language was used due to its extensive AI ecosystem and simplicity. Streamlit serves as the web application framework that enables rapid UI development. The Google Generative AI SDK (google-genai) connects the application to the Gemini 2.5 Flash model. The python-dotenv

library ensures API key confidentiality by loading sensitive credentials from a protected .env file. Pillow (PIL) is utilized to process and preview uploaded images.

The requirements.txt file manages project dependencies and ensures reproducible environments. This modular stack ensures scalability, maintainability, and secure integration.

4.3 Solution Architecture

The system follows a modular client-server architecture. The frontend layer, built using Streamlit, collects user input and artifact images. The backend logic initializes the Gemini client and sends multimodal inputs to the model using the generate_content method.

Data flow begins with user interaction. The uploaded artifact image and optional text query are bundled with a system instruction enforcing academic tone. The Gemini model processes this combined input and returns a structured textual response. The response is rendered dynamically in Markdown format on the web interface.

5. PROJECT PLANNING AND SCHEDULING

5.1 Project Planning

Phase 1: Requirement Analysis

- Identify user needs
- Define functional and non-functional requirements
- Finalize technology stack

Phase 2: Design

- UI layout planning (Streamlit)
- System architecture design
- API integration structure

Phase 3: Development

- Setup project environment
- Implement frontend UI
- Integrate Gemini API
- Write response processing logic

Phase 4: Testing

- Functional testing
- API error handling testing
- Usability testing
- Edge case validation

Phase 5: Documentation

- Prepare project report
- Prepare diagrams
- Final formatting and submission

6. Functional and Performance Testing

Response Time

- Measured time from clicking “Generate” to displaying output.
- Average response time: **6–12 seconds** under normal internet conditions.

Load Testing

- Tested multiple consecutive requests.
- Application remained stable without crashing.

Stress Testing

- Tested with large images and invalid inputs.
- System displayed proper error messages and handled failures gracefully.

UI Performance

- Spinner displayed during processing.

- Long academic outputs rendered smoothly.

7. Results

7.1 Output Screenshots

8. Advantages

The application significantly reduces time required for artifact documentation. It provides a scalable solution for digital museum archiving and educational assignments. The integration of AI enhances productivity in humanities research and digital preservation.

The modular architecture enables easy extension for cloud deployment and additional AI capabilities.

9. Limitations

The system relies on AI-generated interpretation, which may sometimes include factual inaccuracies. It requires internet connectivity and API access. The model does not replace domain experts but assists in drafting.

10. Future Enhancements

Future scope includes citation auto-generation, integration with artifact databases, multilingual support, cloud deployment, user authentication, logging mechanisms, and offline archival export functionality.

11. Conclusion

The Gemini Historical Artifact Descriptor demonstrates the powerful intersection of multimodal AI and digital humanities. By automating artifact documentation through structured academic writing, the project highlights practical applications of generative AI in research, education, and cultural preservation.

The successful integration of Streamlit and Google Gemini API establishes a scalable framework for future AI-driven historical analysis systems.

12. APPENDEX

12.1 Source Code

.env:

```
GOOGLE_API_KEY="api-key-should-not-be-revealed"
```

Requirements.txt:

```
streamlit  
google-genai  
python-dotenv  
Pillow
```

App.py:

```
import streamlit as st  
import os  
from google import genai  
from PIL import Image  
from dotenv import load_dotenv  
  
# Load Environment & Setup Client  
load_dotenv()  
# The new SDK uses a Client object for all interactions  
client = genai.Client(api_key=os.getenv("GOOGLE_API_KEY"))  
  
# Use the latest stable "Flash" model as of Feb 2026  
MODEL_ID = "gemini-2.5-flash"
```
